# ESTIMATING SF-6D HEALTH STATE UTILITY VALUES FOR COMORBID HEALTH CONDITIONS 

Roberta Ara, John Brazier

Health Economics and Decision Science (HEDS)

## BACKGROUND

The prevalence of comorbidities increases with age but preference-based utilities are generally obtained from cohorts who have a single condition. This can cause problems when populating health states in economic models which represent more than one condition. Analysts use the mean utilities from the cohorts with the single conditions to estimate the mean utility for a cohort with comorbidities. There is currently no consensus on which is the most appropriate method to combine these data and the different techniques can produce very different results.

## OBJECTIVE

To compare the accuracy of different methods (minimum, multiplicative, additive, a linear regression) used to estimate health state utility values for comorbid health conditions.

## METHOD

Data collected during five rounds of the Welsh Health

The additive method assumes a constant absolute decrement relative to the baseline:

$$
U_{A, B}^{A L A}=U_{n, n, B B}-\omega_{n A}-U_{A} \mp \boldsymbol{U}_{n b}-U_{B}-
$$

The multiplicative method assumes a constant proportional decrement relative to the baseline:

$$
U_{A, s}^{m a n}=U_{n n, n s} \cdot\left(\frac{U_{A}}{U_{n A}}\right) \cdot\left(\frac{U_{B}}{U_{n B}}\right)
$$

The minimum method assumes the effect on HRQoL is equivalent to the most severe of the single health conditions

$$
U_{A, B}^{\text {Min }}=\min \mathbf{U}_{n A, n B}, U_{A}, U_{B}
$$

A simple linear model obtained using an OLS regression, incorporating a combination of the above methods
$U_{A, B}^{o L S}=\beta_{0}+\beta_{1} \cdot \min \mathbb{U}_{n A}-U_{A} \backslash \boldsymbol{U}_{n b}-U_{B} \rightarrow \beta_{2} \cdot \max \mathbb{U}_{n A}-U_{A} \backslash \mathbf{U}_{n b}-U_{B} \rightarrow \beta_{3} \cdot\left(U_{n A, n B} \cdot \frac{U_{A}}{U_{n A}} \cdot \frac{U_{B}}{U_{n b}}\right)+\varepsilon$ Subscripts: $A=$
not condition B

## RESULTS

|  | Actual | Estimated |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Additive | Multiplicative | Minimum | inear Model |
| Mean SF-6D score | 0.5301 | 0.4039 | 0.4565 | 0.5848 | 0.5301 |
| Min SF-6D score | 0.4368 | 0.3393 | 0.4139 | 0.5620 | 0.4935 |
| Max SF-6D score | 0.6068 | 0.4733 | 0.5038 | 0.6053 | 0.5549 |
| Range: | 0.1700 | 0.1340 | 0.0899 | 0.0433 | 0.0614 |
| Mean error |  | -0.1209 | $-0.0745$ | 0.0546 | 0.0000 |
| Maximum absolute error |  | 0.1924 | 0.1496 | 0.1316 | 0.0669 |
| MAE |  | 0.1209 | 0.0747 | 0.0563 | 0.0191 |
| MSE |  | 0.0157 | 0.0064 | 0.0038 | 0.0006 |
| RMSE |  | 0.1252 | 0.0799 | 0.0613 | 0.0254 |
| Proporion within $0.00 \mid$ |  | 0\% | 3\% | 0\% | 31\% |
| Proportion within [0.025\| |  | 0\% | 6\% | 6\% | 75\% |
| $\xrightarrow{\text { Proportion within MID }} 0.041 \mid$ |  | $3 \%$ | 13\% | 25\% | 88\% |

Figure 1: Actual and estimated SF-6D scores

- The actual mean SF-6D scores for the sub-groups with comorbidities range from 0.465 to 0.607
- The additive method tends to underestimate the scores (ME: -0.121, MAE: 0.121)
- The multiplicative method tends to underestimate the scores (ME: -0.075 , MAE: 0.075)

Table 2: Errors sub-grouped by actual SF-6D

| Actual SF-6D | n | Additive |  |  |  |  |  | Multiplicative |  | Minimum Linear Model |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Mean error |  |  |  |  |  |  |  |  |  |  |  |
| SF-6D $<0.51$ | 7 | -0.1105 | -0.0463 | 0.0880 | 0.0249 |  |  |  |  |  |  |
| $0.51 \leq$ SF-6D $<0.50$ | 18 | -0.1271 | -0.0762 | 0.0528 | 0.0003 |  |  |  |  |  |  |
| $0.50 \leq$ SF-6D | 7 | -0.1399 | -0.0943 | 0.0260 | -0.0256 |  |  |  |  |  |  |
| Mean absolute error |  |  |  |  |  |  |  |  |  |  |  |
| SF-6D $<0.51$ | 7 | 0.1105 | 0.0463 | 0.0880 | $\mathbf{0 . 0 3 0 8}$ |  |  |  |  |  |  |
| $0.51 \leq$ SF-6D $<0.50$ | 18 | 0.1271 | 0.0762 | 0.0528 | $\mathbf{0 . 0 1 2 0}$ |  |  |  |  |  |  |
| $0.50 \leq$ SF-6D | 7 | 0.1399 | 0.0943 | 0.0334 | $\mathbf{0 . 0 2 5 6}$ |  |  |  |  |  |  |
| Accurate to within the MID $\|0.041\|$ |  |  |  |  |  |  |  |  |  |  |  |
| SF-6D $<0.51$ | 7 | $14 \%$ | $43 \%$ | $0 \%$ | $\mathbf{6 7 \%}$ |  |  |  |  |  |  |
| $0.51 \leq$ SF-6D $<0.50$ | 18 | $0 \%$ | $5 \%$ | $16 \%$ | $\mathbf{9 5 \%}$ |  |  |  |  |  |  |
| $0.50 \leq$ SF-6D | 7 | $0 \%$ | $0 \%$ | $71 \%$ | $\mathbf{8 6 \%}$ |  |  |  |  |  |  |

- The minimum method tends to overestimate the scores (ME: 0.055 , MAE: 0.056)
- The linear model performs well in the
 central area but tends to under-predict scores at the top of the range and overpredict scores at the bottom of the range
- The linear model performs best in terms of errors and the proportion of estimated scores within the SF-6D MID (|0.041|) when sub-grouped by actual SF-6D category

## CONCLUSIONS

While the linear model gave the most accurate results in these data, additional research is required to validate these findings.
